The diagnostic value of transvaginal ultrasonography in the differential diagnosis of deep vein thrombosis. Transvaginal ultrasonography (TVUS) was performed in 10 women with clinically suspected venous thrombosis (VT). In one of these patients intraluminal, two-dimensional grey-scale images were also recorded. All cases of VT were verified by intravenous phlebography and/or impedance plethysmography. Prior to the insertion of a large bore intravenous catheter a deep venous thrombosis (DVT) in the proximal part of the femoral vein was seen at the TVUS examination in two cases. Five of the 11 patients with DVT showed intraluminal changes on TVUS and grey-scale imaging. The described technique is compared with phlebography and the results of our examinations confirm the high diagnostic value of TVUS in the diagnosis of DVT.
Q: Show that $\mathbb{E}[X|\mathcal{G}] = \mathbb{E}[X]$ almost surely if \mathcal{G} is increasing. Let $(X_i)_{i \in \mathbb{N}}$ be random variables \mathbb{R} such that $\mathcal{G}_i = \sigma(X_0, \dots, X_i)$ and $\mathcal{H}_i = \sigma(X_0, \dots, X_i, X_{i+1})$. Define $\mathcal{G} = \bigcap_{i \in \mathbb{N}} \mathcal{G}_i$ and $\mathcal{H} = \bigcap_{i \in \mathbb{N}} \mathcal{H}_i$. Show that $\mathbb{E}[X|\mathcal{H}] = \mathbb{E}[X]$ a.s. I believe the following should be true for any \mathcal{G} and \mathcal{H} and not necessarily increasing, but I'm not certain. $\mathbb{E}[X|\mathcal{G}] = \mathbb{E}[X|\mathcal{H}]$ a
